

Réponse thermique de la peau à un flux convectif forcé ou naturel

Principales hypothèses :

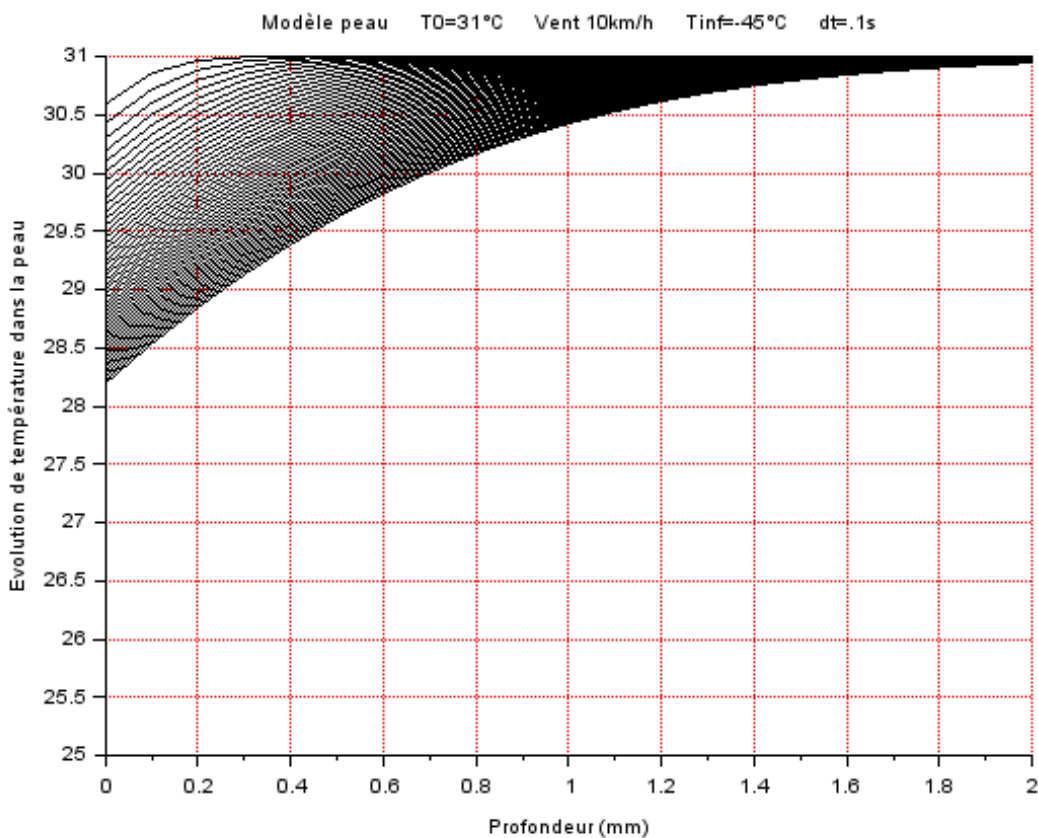

- Convection autour d'un obstacle
- Solution analytique du mur semi-infini (\gg limitation du temps à une propagation du signal à quelques mm en surface)
- $T_0 \text{ peau} = 31^\circ\text{C}$

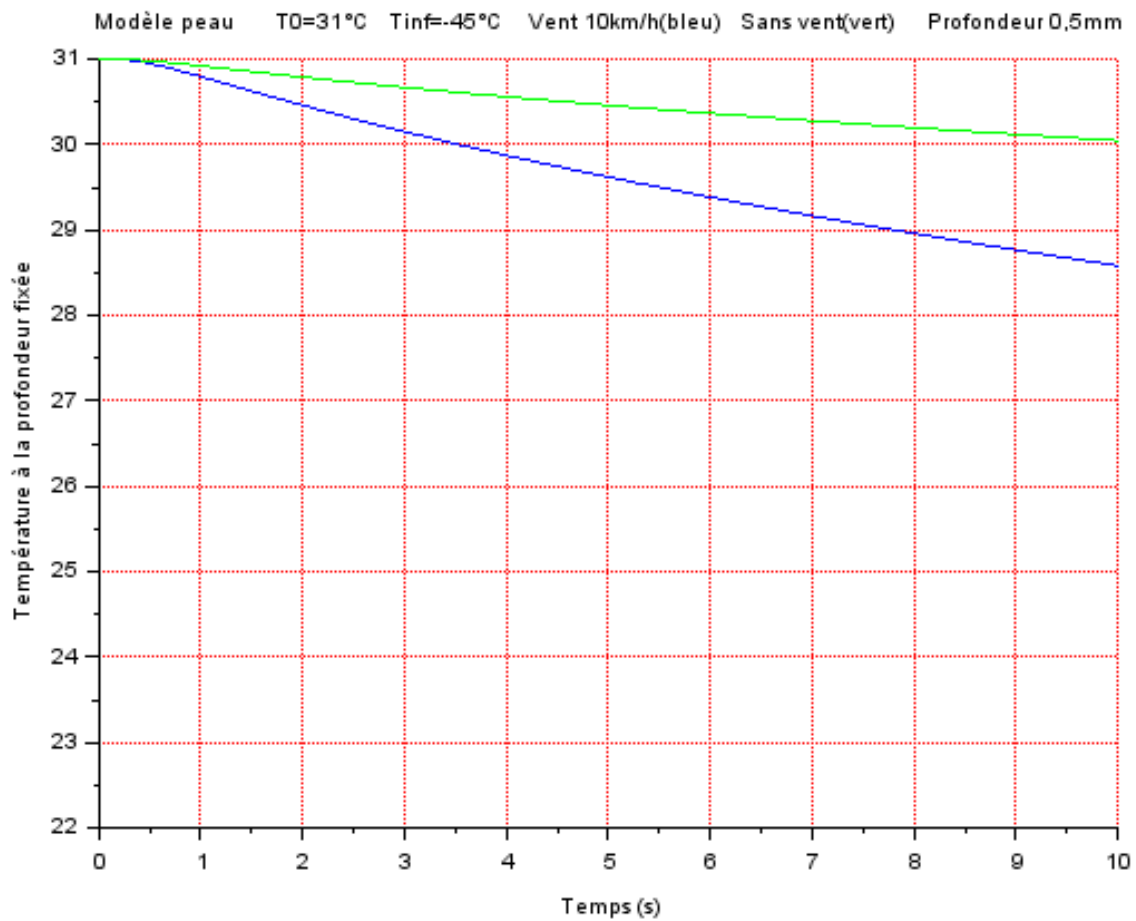

Cas n°1

$T_{\text{inf}} = -45^\circ\text{C}$

Vent nul $\rightarrow h = 7,8 \text{ W/m}^2/^\circ$

Vent = 10 km/h $\rightarrow h = 20,3 \text{ W/m}^2/^\circ$

Flux en parois T0=31°C Tinf=-45°C Vent 10km/h(bleu) Sans vent(vert)

Cas n°2

$T_{inf} = -35^{\circ}\text{C}$

Vent nul > $h = 7,7 \text{ W/m}^2/^{\circ}$

Vent = 60km/h > $h = 75,5 \text{ W/m}^2/^{\circ}$

Flux en parois T0=31°C Tinf=-35°C Vent 60km/h(bleu) Sans vent(vert)
